Acknowledgments

The American Lung Association "State of the Air" 2024 is the result of the hard work of many.

We would like to thank: Allen S. Lefohn, Ph.D., of A.S.L. and Associates, who compiled the data; John Balmes, M.D., who served as expert volunteer reviewer for the health impacts section; Doug Manners, a volunteer writer/editor in Denver, CO, who helped with story collection, and storytellers Rohan Arora, Dr. Aaron Levy, Evelyn Mateos and Mike Nelson.

Great appreciation goes to the National Association of Clean Air Agencies, who strove to make this report better through comments, review and concerns. Many of its members reviewed and commented on the individual state data presented and the methodology to make this report more accurate. We also appreciate the assistance of members of the Association of Air Pollution Control Agencies, who also reviewed data from their states. We appreciate them all as our partners in the fight against air pollution. This report should in no way be construed as a comment on the work any of these agencies do.

"State of the Air" 2024 would not have been possible but for the twenty years of inspiration, dedication and hard work of the late Janice E. Nolen. We still miss her every day.

The American Lung Association assumes sole responsibility for the content of "State of the Air" 2024.

EMBARGOED

Why "State of the Air"?

The Clean Air Act requires the U.S. Environmental Protection Agency (EPA) to set health-based limits, called National Ambient Air Quality Standards (NAAQS), for six dangerous outdoor air pollutants: particulate matter, ozone, nitrogen oxides, sulfur dioxide, carbon monoxide and lead. "State of the Air" looks at two of the most widespread and dangerous pollutants from this group, fine particulate matter and ozone.

The NAAQS identify what is considered a safe level of each pollutant to breathe, based on the most recent health and medical science, including an adequate margin of safety for those most at risk. These standards require states and local governments to take steps to reduce emissions to attain the standards. The standards also serve to alert families with children, seniors, individuals with lung or heart conditions, and others about dangerous air pollution levels through color-coded air quality alerts. This enables them to take necessary precautions to minimize their exposure. Under the Clean Air Act, the standards must be based solely on what is needed to protect health and must be periodically updated as the science evolves.[i]

Setting national health-based standards and requiring states that violate the standards to enact plans to clean up their air pollution problems have been a great benefit to the public health of the nation. Since the Clean Air Act was passed in 1970, the combined emissions of six key air pollutants have fallen by 78%, according to EPA. But as "State of the Air" 2024 shows, millions of people in this country are still breathing unhealthy air.

EMBARGOED

Purpose and history of "State of the Air"

In the year 2000, the American Lung Association launched its annual "State of the Air" report to provide the public with easy-to-understand information about the quality of the air in their communities based on the credible data and sound science that EPA is required to use to set and enforce the air quality standards.

For the first several years, "State of the Air" focused solely on ozone pollution and included data for five populations at increased risk – children, older adults, children with asthma, adults with asthma and people with emphysema. In 2004, changes to the air quality standards and the deployment of air pollution monitoring enabled the addition of short-term and year-round fine particle pollution to the report. Over time, accumulating scientific evidence has shown significant health harms from both ozone and particle pollution among other groups of vulnerable individuals. "State of the Air" has accommodated this new information by gradually adding populations-at-risk categories to its reporting. "State of the Air" 2024 now includes data for 10 vulnerable groups.

Since its inception 25 years ago, "State of the Air" has been tremendously successful in raising awareness about particle pollution and ozone, two of the most dangerous and pervasive air pollutants nationwide. The American Lung Association is proud and grateful that the public, the media, clean air advocates and decision-makers have used this report every day, year after year, to call attention to the work that remains to be done to protect the public from the threat of air pollution.

How "State of the Air" can be used

We write and release "State of the Air" every year to make information on air quality and health clear and accessible to everyone. We show the progress each community has made and how much more needs to be done to achieve healthy air. In this report, you'll find information on local air quality nationwide. You'll also

i In February 2024, after a lengthy wait, EPA announced a new, more protective annual standard for fine particle pollution. That standard is being used in the 2024 "State of the Air" report. The ozone standard is also overdue for a revision based on the science, but that process has faced multiple delays.

find the latest research on how air pollution affects health. With these tools, you can take proactive steps to safeguard both your lungs and your family's lungs from unhealthy air.

This report also includes ideas for how you can become a champion for clean air. First, we have suggestions for concrete actions you can take to reduce your own contributions to air pollution and climate change. And second, we invite you to take advocacy action with the American Lung Association. Our report includes policy recommendations for every level of government. Your voice is powerful, and when you tell your leaders that your lungs depend on stronger limits on air pollution, you make a compelling case. Please share your story and add your name to our petition—and then, take the next step. Reach out to your representatives at every level of government, share the "State of the Air" results for your community, and call on them to take action to protect public health.

State of the Air 2024 Methodology

Statistical Methodology: The Air Quality Data

Data Sources

Ozone and short-term particle pollution. The data on air quality throughout the United States were obtained from the U.S. Environmental Protection Agency's Air Quality System (AQS). The American Lung Association contracted with Allen S. Lefohn, Ph.D., A.S.L. & Associates, Helena, Montana, to characterize the hourly averaged ozone concentration information and the 24-hour averaged fine particulate matter ($PM_{2.5}$) concentration information for the three-year period for 2020-2022 for each monitoring site.

Year-round particle pollution. Design values for the annual $PM_{2.5}$ concentrations by county for the period 2020-2022 were retrieved December 18, 2023 from data posted on May 23, 2023, at the U.S. Environmental Protection Agency's website at https://www.epa.gov/air-trends/air-quality-design-values.

The Lung Association received important assistance from members of the National Association of Clean Air Agencies and the Association of Air Pollution Control Agencies. With their assistance, all state and local agencies were provided the opportunity to review and comment on the data in draft tabular form. The Lung Association reviewed any discrepancies with the agencies and, if needed, with Dr. Lefohn at A.S.L. & Associates. The American Lung Association wishes to express its continued appreciation to the state and local air directors for their willingness to assist in ensuring that the characterized data used in this report are correct.

Ozone Data Analysis

The 2020, 2021 and 2022 AQS hourly ozone data were used to calculate the daily 8-hour maximum concentration for each ozone-monitoring site. The hourly averaged ozone data were downloaded on June 26, 2023, following the close of the authorized period for quality review and assurance certification of data. Only the hourly average ozone concentrations derived from FRM and FEM monitors were used in the analysis. The data were considered for a three-year period for the same reason that EPA uses three years of data to determine compliance with the ozone standard: to prevent a situation in which anomalies of weather or other factors in any single year create air pollution levels that inaccurately reflect typical conditions. The highest 8-hour daily maximum concentration in each county was identified for each day of the EPA-defined ozone season for 2020, 2021 and 2022.

The current National Ambient Air Quality Standard for ozone is 70 parts per billion (ppb) measured over eight hours. EPA's Air Quality Index reflects the 70 ppb standard. A.S.L. & Associates prepared a table by county that summarized, for each of the three years, the number of days during the ozone season when the ozone level was within the ranges identified by EPA based on the Air Quality Index:

8-hour Ozone Concentration	Air Quality Index Levels
0-54 ppb	Good (Green)
55-70 ppb	Moderate (Yellow)
71-85 ppb	Unhealthy for Sensitive Groups (Orange)
86-105 ppb	Unhealthy (Red)
106-200 ppb	Very Unhealthy (Purple)
>200 ppb	Hazardous (Maroon)

EMBARGOED

The approach of this report was to identify the number of days that 8-hour daily maximum concentrations in each county occurred within the defined ranges. This provided an indication of the level of pollution for all monitored days, not just those days that fell under the requirements for attaining the National Ambient Air Quality Standards. Therefore, no data capture criteria were applied to eliminate monitoring sites or to require a number of valid days for the ozone season.

The daily maximum 8-hour average concentration for a given day is derived from the highest of the 17 consecutive 8-hour averages beginning with the 8-hour period from 7:00 a.m. to 3:00 p.m. and ending with the 8-hour period from 11:00 p.m. to 7:00 a.m. the following day. This follows the process EPA uses for the current ozone standard adopted in 2015. All valid days of data within the ozone season were used in the analysis. However, for computing an 8-hour average, at least 75 percent of the hourly concentrations (i.e., 6-8 hours) had to be available for the 8-hour period. In addition, an 8-hour daily maximum average was identified if valid 8-hour averages were available for at least 75 percent of possible hours in the day (i.e., at least 13 of the possible 17 8-hour averages). Because EPA includes days with inadequate data (i.e., not 75 percent complete) if the standard value is exceeded, our data capture methodology also included the site's 8-hour value if at least one valid 8-hour period were available, and it was 71 ppb or higher.

As instructed by the Lung Association, A.S.L. & Associates included the exceptional (e.g., wildfires) and natural events (e.g., stratospheric intrusions) that were identified in the database and identified for the Lung Association the dates and monitoring sites that experienced such events. Some data have been flagged by the state or local air pollution control agency to indicate that they had raised issues with EPA about those data. For each day across all sites within a specific county, the highest daily maximum 8-hour average ozone concentration was recorded and then the results were summarized by county for the number of days the ozone levels were within the ranges identified above.

Following receipt of the above information, the American Lung Association identified the number of days each county with at least one ozone monitor experienced air quality designated as orange (Unhealthy for Sensitive Groups), red (Unhealthy) or purple (Very Unhealthy). When insufficient data were available in any year, an "incomplete" was identified for the 3-year period. Insufficient data exist for various reasons. For example, when a specific monitor was used for a special study and the monitor was then discontinued in other years, an "incomplete" is assigned.

EMBARGOED

Short-Term Particle Pollution Data Analysis

A.S.L. & Associates identified the maximum daily 24-hour AQS $PM_{2.5}$ concentration for each county for each day in 2020, 2021 and 2022 with monitoring information. The 24-hour averaged $PM_{2.5}$ data were downloaded on August 2, 2023, following the close of the authorized period for quality review and assurance certification of data. The hourly averaged $PM_{2.5}$ concentration data in the EPA AQS database were characterized into 24-hour average $PM_{2.5}$ values by EPA and provided to A.S.L. & Associates. Using these results, A.S.L. & Associates prepared a table by county that summarized, for each of the three years, the number of days the maximum of the daily $PM_{2.5}$ concentration was within the ranges identified by EPA based on the Air Quality Index, as adopted by EPA on December 14, 2012[ii]:

ii Analysis of the daily $PM_{2.5}$ data for "State of the Air" 2024 was completed in January 2024, before EPA announced the finalization of the revised $PM_{2.5}$ NAAQS and Air Quality Index. The values used in this report are based on the 2012 Air Quality Index.

24-hour $PM_{2.5}$ Concentration	Air Quality Index Levels
0.0 µg/m³ to 12.0 µg/m³	Good (Green)
12.1 µg/m³ to 35.4 µg/m³	Moderate (Yellow)
35.5 µg/m³ to 55.4 µg/m³	Unhealthy for Sensitive Groups (Orange)
55.5 µg/m³ to 150.4 µg/m³	Unhealthy (Red)
150.5 µg/m³ to 250.4 µg/m³	Very Unhealthy (Purple)
greater than or equal to 250.5 µg/m³	Hazardous (Maroon)

All previous data collected for 24-hour average $PM_{2.5}$ were characterized using the AQI thresholds listed above.

The goal of this report was to identify the number of days that the maximum in each county of the daily $PM_{2.5}$ concentration occurred within the defined ranges. This approach provided an indication of the level of pollution for all monitored days, not just those days that fell under the requirements for attaining the National Ambient Air Quality Standards. Therefore, no data capture criteria were used to eliminate monitoring sites. Both 24-hour averaged PM data, as well as hourly averaged PM data averaged by EPA over 24 hours, were used. Included in the analysis are data collected using only FRM and FEM methods, which reported hourly and 24-hour averaged data. As instructed by the Lung Association, A.S.L. & Associates included the exceptional and natural events that were identified in the database and identified for the Lung Association the dates and monitoring sites that experienced such events. Some data have been flagged by the state or local air pollution control agency to indicate that they had raised issues with EPA about those data. For each day across all sites within a specific county, the highest daily maximum 24-hour $PM_{2.5}$ concentration was recorded and then the results were summarized by county for the number of days the concentration levels were within the ranges identified above.

Following receipt of the above information, the American Lung Association identified the number of days each county with at least one $PM_{2.5}$ monitor experienced air quality designated as orange (Unhealthy for Sensitive Groups), red (Unhealthy), purple (Very Unhealthy) or maroon (Hazardous).

EMBARGOED

Description of County Grading System

Ozone and Short-Term Particle Pollution (24-hour $PM_{2.5}$)

The grades for ozone and short-term particle pollution (24-hour $PM_{2.5}$) were based on a weighted average calculation. To determine weighted averages, the Lung Association followed these four steps separately for each pollutant in each county:

1. Assigned weighting factors to each category of the Air Quality Index. Days of poor air quality were given the following weighting factors:

   Orange days 1.0
   Red days 1.5
   Purple days 2.0
   Maroon days 2.5

   This ensured that days when the air pollution levels were worse received appropriately greater weight.

2. Multiplied the total number of days within each AQI category by its assigned factor, and added all the categories to calculate a total:

   Total = [Orange days x 1] + [Red days x 1.5] + [Purple days x 2] + [Maroon days x 2.5]

3. Divided the total by three to determine the weighted average, since the monitoring data were collected over a three-year period:

Weighted Average = Total ÷ 3

Weighted average was then used to determine each county's grades for ozone and 24-hour $PM_{2.5}$ according to the following table:

Weighted Average	Grade
0.0	A
0.3 to 0.9	B
1.0 to 2.0	C
2.1 to 3.2	D
3.3 or higher	F

All counties with a weighted average of zero (corresponding to no exceedances of the standard over the three-year period) were given a grade of "A."

For ozone, an "F" grade was set to generally correlate with the number of unhealthy air days that would place a county in nonattainment for the ozone standard.

For short-term particle pollution, fewer unhealthy air days are required for an F than for nonattainment under the $PM_{2.5}$ standard. The 2012 national air quality standard is set to allow two percent of the days during the three years to exceed 35 µg/m^3 (called a "98th percentile" form) before violating the standard. That could be as many as 21 unhealthy days in three years. The grading used in this report is roughly equivalent to allowing only about one percent of the days to be those on which $PM_{2.5}$ concentrations were over 35 µg/m^3 (called a "99th percentile form"). The American Lung Association supports using the 99th percentile form as a more appropriate form of the standard that is intended to protect the public from short-term episodes or spikes in pollution.

Weighted averages allow comparisons to be drawn based on severity of air pollution. For example, if one county had nine orange days and no red days, it would earn a weighted average of 3.0 and a D grade. However, another county that had only eight orange days but also two red days, which signify days with more serious air pollution, would receive an F. That second county would have a weighted average of 3.7.

Note that this system differs significantly from the methodology EPA uses to determine violations of both the ozone and the 24-hour $PM_{2.5}$ standards. EPA determines whether a county violates the ozone standard based on the fourth maximum daily 8-hour ozone reading each year averaged over three years. Multiple days of unhealthy air beyond the highest four in each year are not considered. By contrast, the system used in this report recognizes when a community's air quality repeatedly results in unhealthy air throughout the three years. Consequently, some counties will receive grades of "F" in this report, showing repeated instances of unhealthy air, even while still meeting the EPA's 2015 ozone standard. This is consistent with the American Lung Association's position is that the evidence shows that the 2015 ozone standard fails to adequately protect public health.

Counties were ranked by weighted average. Metropolitan areas were ranked by the highest weighted average among the counties within a given Metropolitan Statistical Area as of 2020 as defined by the White House Office of Management and Budget (OMB).

Weighted average values from earlier years are from prior reports and updated when new standards are implemented.

EMBARGOED

Year-Round Particle Pollution (Annual $PM_{2.5}$)

Since no comparable Air Quality Index exists for year-round particle pollution (annual $PM_{2.5}$), the grading was based on the 2024 National Ambient Air Quality Standard for annual $PM_{2.5}$ of 9 µg/m^3. Counties that EPA listed as being at or below 9 µg/m^3 were given grades of "Pass." Counties that EPA listed as being above 9 µg/m^3 were given grades of "Fail." Where data was collected but was insufficient for EPA to determine a design value, those counties received a grade of "Incomplete."

A design value is the calculated concentration of a pollutant based on the form of the National Ambient Air Quality Standard and is used by EPA to determine whether the air quality in a county meets the standard. Counties were ranked by design value. Metropolitan areas were ranked by the highest design value among the counties within a given Metropolitan Statistical Area as of 2020 as defined by the OMB.

Statistical Methodology: Population Data

The Lung Association calculates the county population at risk from these pollutants based on the population from the entire county where the monitor is located. The Lung Association then calculates the metropolitan population at risk based upon the largest metropolitan area that contains that county. Not only do people from that county or metropolitan area circulate within the county and the metropolitan area, but the air pollution also circulates to that monitor from throughout the county and metropolitan area.

Details about how the populations-at-risk numbers are derived can be found in **Understanding Grades and Tables**.

EMBARGOED

Key Findings

Nearly **4 in 10** people live in places with unhealthy levels of air pollution

People of color were 2.3 times as likely as white people to live in a county with 3 failing grades.

Climate change is making the job of cleaning up the air more difficult.

The "State of the Air" 2024 report finds that despite decades of progress cleaning up air pollution, 39% of Americans—131.2 million people—still live in places with failing grades for unhealthy levels of ozone or particle pollution. This is 11.7 million more people breathing unhealthy air compared to last year's report.

The significant rise in the number of individuals whose health is at risk is the result of a combination of factors. Extreme heat, drought and wildfires are contributing to a steady increase in deadly particle pollution, especially in the western U.S. Also, this year's "State of the Air" report is using EPA's new, more protective national air quality standard for year-round levels of fine particle pollution, which allows for the recognition that many more people are breathing unhealthy air than was acknowledged under the previous weak standard.

Again this year, "State of the Air" finds that the burden of living with unhealthy air is not shared equally. Although people of color make up 41.6% of the overall population of the U.S., they are 52% of the people living in a county with at least one failing grade. In the counties with the worst air quality that get failing grades for all three measures of air pollution, 63% of the nearly 44 million residents are people of color, compared to 37% who are white.

The "State of the Air" report looks at two of the most widespread and dangerous air pollutants, fine particles and ozone. The air quality data used in the report are collected at official monitoring sites across the United States by the federal, state, local and Tribal governments. The Lung Association calculates values reflecting the air pollution problem and assigns grades for daily and long-term measures of particle pollution and daily measures of ozone. Those values are also used to rank cities (metropolitan areas) and counties. This year's report presents data from 2020, 2021 and 2022, the most recent quality-assured nationwide air pollution data publicly available. See ***About This Report*** for more detail about the methodology for data collection and analysis.

"State of the Air" 2024 is the 25th edition of this annual report, which was first published in 2000. From the beginning, the findings in "State of the Air" have reflected the successes of the Clean Air Act, as emissions from transportation, power plants and manufacturing have been reduced. In recent years, however, the findings of the report continue adding to the evidence that a changing climate is making it harder to protect human health. High ozone days and spikes in particle pollution related to extreme heat, drought and wildfires are putting millions of people at risk and adding challenges to the work that states and cities are doing across the nation to clean up air pollution.

EMBARGOED

> When we started doing "State of the Air" in 2000, I never imagined that in the 25th edition we would be reporting that more than 100 million people are still breathing unhealthy air. It's unacceptable.
>
> **Paul Billings,**
> **American Lung Association**

The combination of policy-driven reductions in emissions on the one hand and climate change-fueled increases in pollution on the other hand have resulted in an ongoing and marked disparity between air quality in eastern and western states, especially for the daily measure of fine particle pollution. In this year's report, only 4 large counties in three states east of the Mississippi River, earned failing grades for daily spikes in fine particle pollution, compared to 108 counties in 16 western states.

When looking at levels of year-round particle pollution, however, the story becomes more nuanced. The majority of the 119 counties earning failing grades for year-round particle pollution are in the western U.S., but the new, stronger standard is revealing remaining air quality problems in eastern and midwestern states. In "State of the Air" 2024 there were 47 counties in 12 states east of the Mississippi River with unhealthy year-round levels of fine particles.

In "State of the Air" 2024, the metropolitan areas that ranked worst in the country for each of the three pollutant measures were unchanged from last year's report. Bakersfield, California topped the list for worst short-term particle pollution again this year. Bakersfield also continued as the metropolitan area with the worst level of year-round particle pollution for the 5th year in a row. Los Angeles remains the city with the worst ozone pollution in the nation, as it has been in 24 of the 25 years of reporting in "State of the Air"– even though city residents are exposed to unhealthy levels of ozone an average of 55 days a year fewer than now than they were in 2000.

Short-term Particle Pollution Trends

65 million people live in counties with **F grades** for daily particle pollution.

In the years 2020, 2021 and 2022, there were 65 million people living in the 112 counties in 19 states that earned an F grade for unhealthy spikes in particulate matter air pollution. This represents an increase of 1.3 million more people than in last year's report, the sixth straight year of increasing health threat of this deadly pollutant.

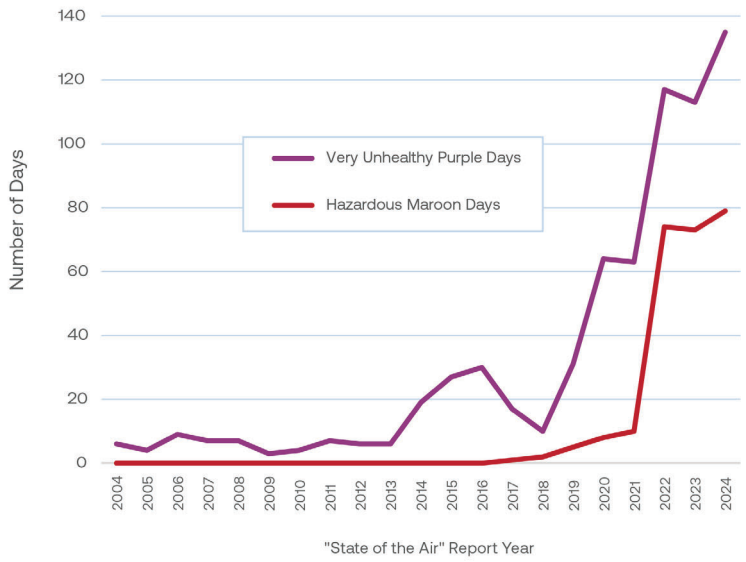
Even compared with the past several years of "State of the Air" reports—in which many cities and counties experienced their highest weighted average number of days ever reported for fine particle pollution—results this year were again worse, especially throughout much of the western United States. This trend in recent years is a reversal after roughly a decade of improvements resulting from the requirements of the Clean Air Act.

In 2004, with data from 2001, 2002 and 2003, the "State of the Air" report added grades and ranks for fine particle pollution. It was the first time three years of data was available from a network of monitors put in place following EPA's adoption in 1997 of a new health standard to address particle pollution. At that time, 106 counties in 30 states earned an F grade for short-term particle pollution, affecting the health of 81 million people. The air quality standard was weaker than it is now, meaning that in fact many more people were breathing unhealthy air. If the current standard had been in effect, 189 counties in 36 states would have gotten failing marks.

EMBARGOED

Wildfires in the western United States and Canada remain the major contributing factor to the increasing number of days and places with unhealthy levels of particle pollution in recent years. Wildfires are also continuing to increase the severity of pollution, resulting in the highest ever number of days designated as either purple or maroon (135 and 79 days, respectively). These are the levels on the Air Quality Index that carry the strongest health warnings. On purple Very Unhealthy days, "the risk of health effects is increased for everyone." On maroon Hazardous days, the highest category, a health warning of emergency conditions is issued, saying, "Everyone is more likely to be affected."

Most Ever Days with Worst Levels of Daily Particle Pollution

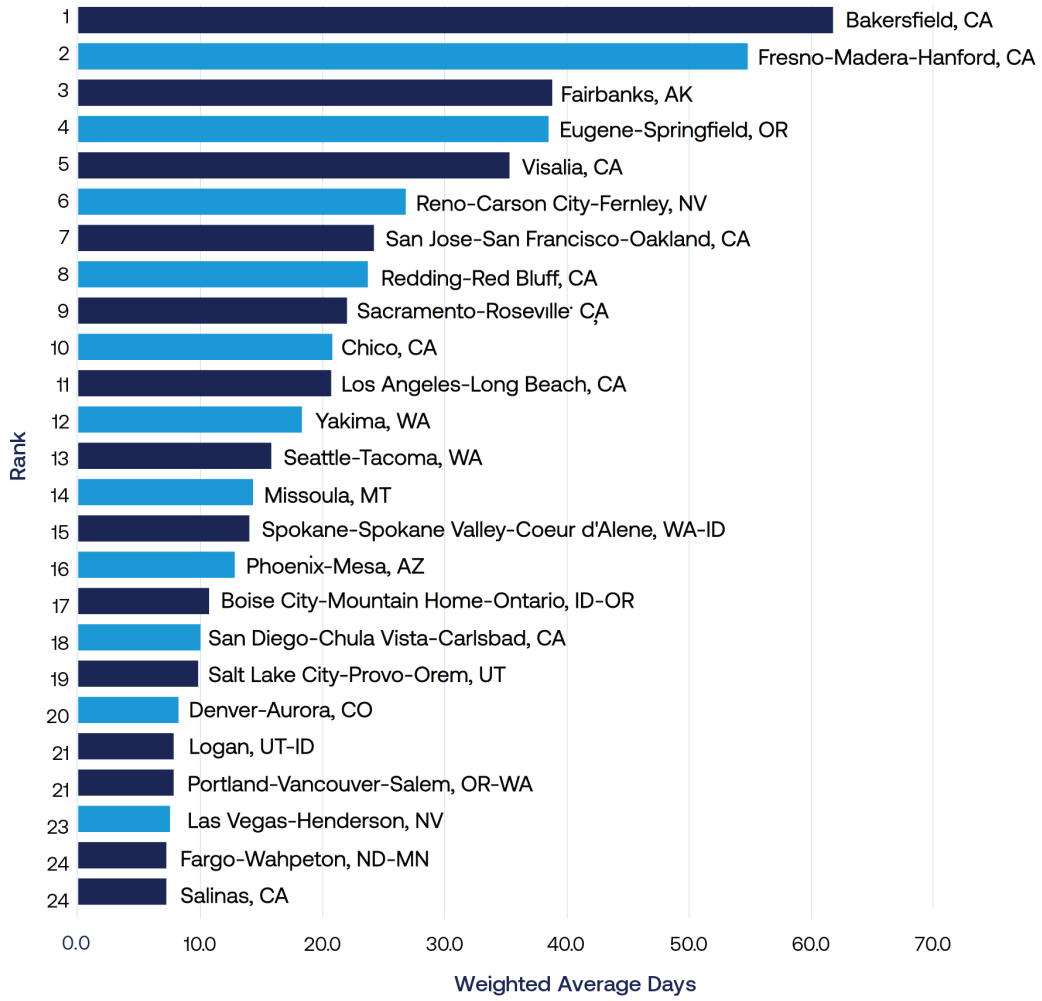


In the years 2020, 2021 and 2022, the health of 32.3 million people across 58 counties in ten states was put at risk on "purple" or "maroon" days for fine particle pollution. This is slightly worse than the findings in last year's "State of the Air" and a worrisome sign of a trend that is continuing as climate change worsens.

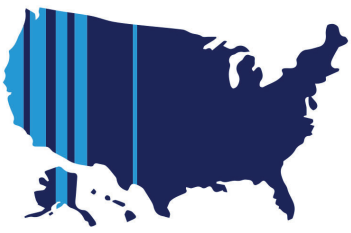
In this year's report, thirty-three metropolitan areas equaled or exceeded their previous worst-ever weighted average number of days with unhealthy levels of fine particle pollution. Among those cities ranked the worst 25, the average number of days per year that residents were exposed to high levels of fine particle pollution increased by more than two days, to a weighted average of 20.8 days. Seven of the 25 most polluted cities for this measure posted their highest-ever number of unhealthy days: Fairbanks, Alaska; Visalia, California; Boise City, Idaho; Eugene, Oregon; Las Vegas and Reno, Nevada and Spokane, Washington. Only one city, Logan, Utah, recorded its fewest-ever number of unhealthy days, though it still earned an "F" grade.

EMBA

25 Cities Most Polluted by Daily PM



All the 25 worst cities for short-term particle pollution are in the Western U.S.



Twenty-two of last year's worst 25 cities remained listed among the worst 25 in this year's report, with most of their relative ranks shifting by no more than two places. Three metro areas saw declines in their air quality that moved them up among the worst 25: Las Vegas, Nevada, for the first time, and well as Portland, Oregon and Seattle, Washington. Medford, Oregon, and Lancaster and Pittsburgh, Pennsylvania improved enough to leave the list. Pittsburgh, in 26th place this year, narrowly avoided the 25 worst list, noteworthy as first time that Steel City has earned that distinction for this measure.

In "State of the Air" 2024, with the departure of Lancaster and Pittsburgh, for the first time in the report's history, no cities among the 25 worst for short-term particle pollution were in the eastern United States. The farthest east of any metro area on the list was Fargo-Wahpeton, ND-MN.

The New National Standard for Particle Pollution in "State of the Air"

In February 2024, the U.S. EPA made a long-overdue update to the National Ambient Air Quality Standards for fine particle pollution. In the final rule, EPA revised the annual standard from 12 to 9 micrograms per cubic meter (µg/m3) and opted not to revise the current 24-hour standard of 35 µg/m3. Although this stronger annual standard will yield significant health benefits to millions of people nationwide, it falls short of what the American Lung Association and other health organizations were calling for, based on existing science (see ***Health Impact of Air Pollution***).

The grades and rankings for annual particle pollution in "State of the Air" 2024 were calculated using the new 9 µg/m3 standard. As a result, many more places across the country earned a failing grade this year compared to the year before, a change that more accurately reflects the actual health risk from breathing the air in those communities.

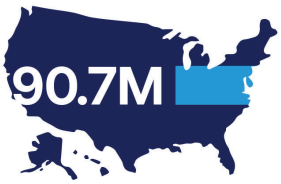
Another component of EPA's new rule was some changes to the Air Quality Index (AQI) to better reflect recent health science on exposure to fine particles. EPA made adjustments to the breakpoints between the color-coded categories, so that the health warnings associated with those categories will be issued at lower pollution levels than they were previously. After the changes go into effect in April 2024, the breakpoint between green Good and yellow Moderate was changed to align with the updated annual standard. Furthermore, some days that would have been red Unhealthy days will be declared purple Very Unhealthy days, and some purple Very Unhealthy days will be recognized as maroon Hazardous days.

The updated Air Quality index is not reflected in this year's report, but will be applied to the grades and weighted averages for short-term particle pollution in next year's "State of the Air".

EMBARGO

Year-round Particle Pollution Trends

Nearly 90.7 million people live in counties with failing grades for year-round particle pollution



With the recent adoption of a more protective air quality standard for year-round levels of fine particle pollution, "State of the Air" 2024 finds that nearly 90.7 million people are living in 119 counties where year-round particle pollution levels do not meet the national air quality standard, and therefore receive a failing grade. This is a dramatic increase from last year's report that, using the previous weaker standard, identified slightly fewer than 18.8 million people living in 17 counties with failing marks for year-round levels of fine particle pollution.

Most of the additional 71.9 million more people now included in the total population living in areas with failing grades for year-round particle pollution have in fact been breathing unhealthy air for years. The big change this year is the standard, and the overdue recognition of the health risk from year-round exposure to this deadly pollutant. The severity of annual particle pollution only worsened slightly in this year's report. When looking nationwide at all the counties with measurements for this pollutant, there was little change in the national average of those counties' year-round levels, with about an equal number improving as got worse.

In 2004, with data from 2001, 2002 and 2003, the "State of the Air" report added grades and ranks for fine particle pollution. It was the first time three years of data was available from a new network of monitors put in place following EPA's adoption of a new health standard to address particle pollution in 1997. At that time, 120 counties in 22 states earned an F grade for annual particle pollution, affecting the health of 66 million people. The air quality standard was weaker than it is now, meaning that in fact many more people were breathing unhealthy air. If the 2024 standard had been in effect at that time, 365 of the monitored counties in 47 states would have gotten failing marks.

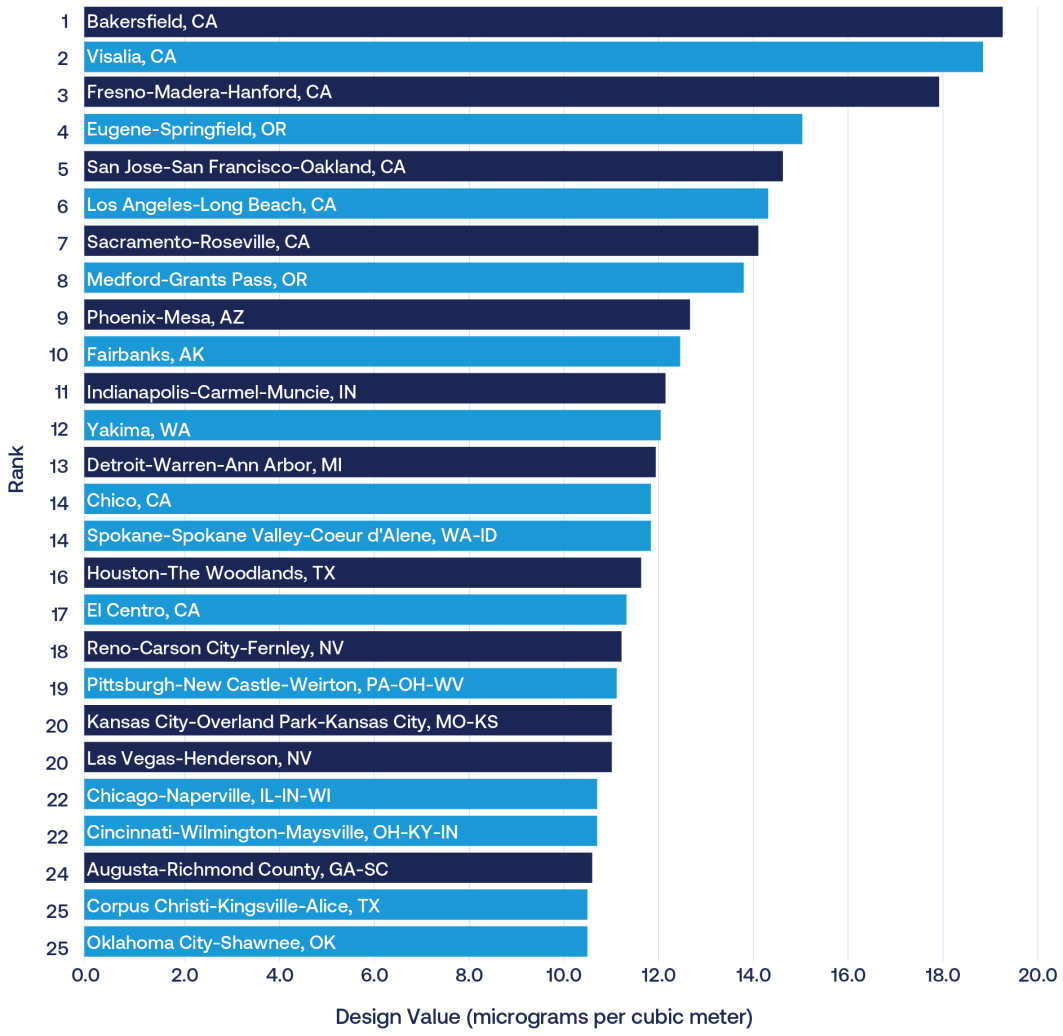
By its nature, the year-round measure of average particle pollution is not as volatile as the daily measure. Changes over time may look smaller, but because they typically represent recurring exposures over many days and weeks, seemingly minor differences can have a big impact on public health. In "State of the Air" 2024, the most polluted cities for year-round particle pollution continued the worsening trend of recent years by an average of about 0.25 micrograms per cubic meter (from 12.3 to 12.55 µg/m3), with 16 metro areas worsening compared with 7 improving.

Five of the 26 most polluted cities for this measure posted their worst-ever levels of year-round particle pollution. Yakima, Washington remained unchanged from last year's value, making this the third consecutive year at the same record level. The other four in the worst-ever group were Sacramento, California; Reno, Nevada; Eugene, Oregon; and Spokane, Washington. Of these four, only Sacramento had also posted a new worst-ever performance in last year's report.

In contrast, seven of the 26 most polluted cities had lower year-round levels compared to last year. Three of these tied or exceeded their previous best-ever performance in "State of the Air" 2024: Los Angeles, California; Cincinnati, Ohio and Pittsburgh, Pennsylvania. Nevertheless, all 26 of the worst-ranked metro areas, along with 46 others, had poor enough long-term average particle pollution levels to earn failing grades in this year's report.

EMBARGOED

25 Cities Most Polluted by Annual PM



Twenty of last year's worst 25 cities remained listed among the 26 (because of a tie for 25th place) in this year's report. Even though most of their relative ranks shifted by no more than two places, there were some significant changes among the other metro areas. Eugene, Oregon's increase in its annual average level of fine particle pollution was worst in the country, resulting in its rank dropping from 15th worst in last year's report to 4th worst in "State of the Air" 2024. In contrast, Birmingham, Alabama's improvement to its best-ever annual average level of particle pollution was the largest in the country and resulted in its rank improving from 18th to 96th worst.

Five metro areas improved enough to leave the worst-cities list for this measure. In addition to Birmingham, they were Louisville, Kentucky; Bend, Oregon; and Laredo and McAllen, Texas. Six metro areas replaced them, five of them debuting on the list: Kansas City; Reno, Nevada; Oklahoma City, Oklahoma; Corpus Christi, Texas; and Spokane, Washington. Las Vegas, Nevada rejoined the list for the first time since the 2018 "State of the Air" report.

Unlike the worst 25 cities for the daily measure of particle pollution that were all in the west, the 25 worst cities for annual particle pollution were somewhat more widely distributed around the country. Cities predominantly affected by western drought and wildfires, notably eight in California, and two each in Nevada, Oregon, and Washington, still made up the highest share. However, cities less

affected by wildfire smoke in this year's report, but still grappling with pollution from local industrial and mobile sources, continued to show up on this list. There were ten of these spread among nearly as many states: Indianapolis, Detroit, Houston, Pittsburgh, Kansas City, Cincinnati, Chicago, Augusta, Corpus Christi, and Oklahoma City.

Ozone Pollution Trends

Exposure to unhealthy levels of ozone air pollution continues to make breathing difficult for more Americans across the country than any other single pollutant. In the years 2020, 2021, and 2022, some 100.6 million people lived in the 125 counties in 26 states that earned an "F" grade for ozone. This means that three of every ten people, including 22.5 million infants and children, 15.5 million people age 65 or older, and tens of millions in other groups at highest risk of health harm, are exposed to high levels of ozone on enough days to earn the air they breathe a failing grade.

More than 100 million people live in counties with **F grades** for ozone smog.

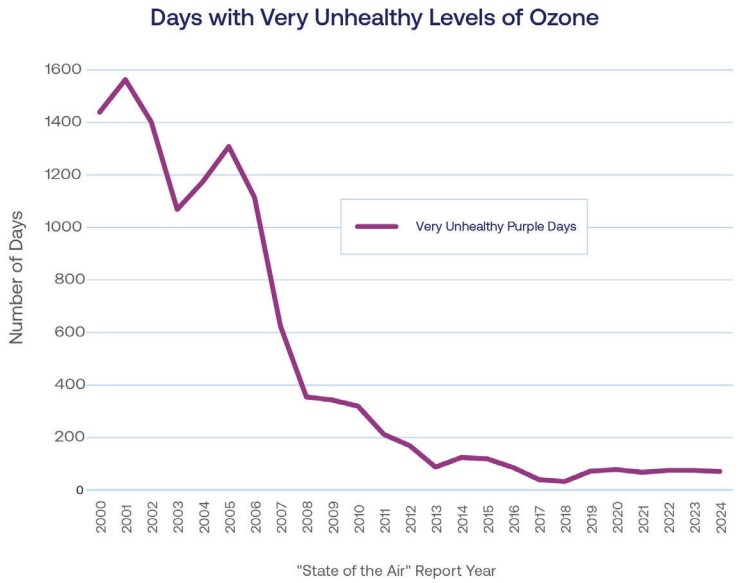
Although ozone air pollution remains a serious threat to public health, one trend in this year's "State of the Air" report is continuing in a positive direction. For the fourth consecutive report, the number of people living in counties with a failing grade for ozone declined, this year by 2.4 million people.

Ambient ozone levels are influenced by a complex interaction of natural and human-driven factors that can vary from year to year, with some years being better overall than others. However, the long-term trend of improvement in ozone levels can be attributed to the fact that the Clean Air Act has been working. Controls placed on emissions have increasingly resulted in the replacement of more polluting engines, fuels, and industrial processes nationwide. The transition of the economy away from coal-fired power plants, the dirtiest fossil fuel, and towards clean renewable sources of energy, has unquestionably had an impact, especially in parts of the eastern United States.

When the first "State of the Air" report was released in 2000, with ozone data from 1996, 1997 and 1998, 332 counties in 38 states earned an F grade, putting the health of 132.5 million people at risk. The air quality standard was weaker than it is now, meaning that in fact many more people were breathing unhealthy air. If the current standard had been in effect at that time, 463 counties in 43 states would have gotten failing marks. Of the counties where data was being collected, only 9 would have received an A.

In many parts of the country, the weighted average number of days of unhealthy ozone has declined substantially over the years. It is worth noting that the severity of ozone pollution has also dropped. In 2001, the "State of the Air" report recorded a 25-year high of 1,563 very unhealthy Purple days for ozone around the country. In 2024, that number has dropped to a 25-year low of 71 days. That is still 71 days too many, but an important indicator of progress.

EMBARGOED

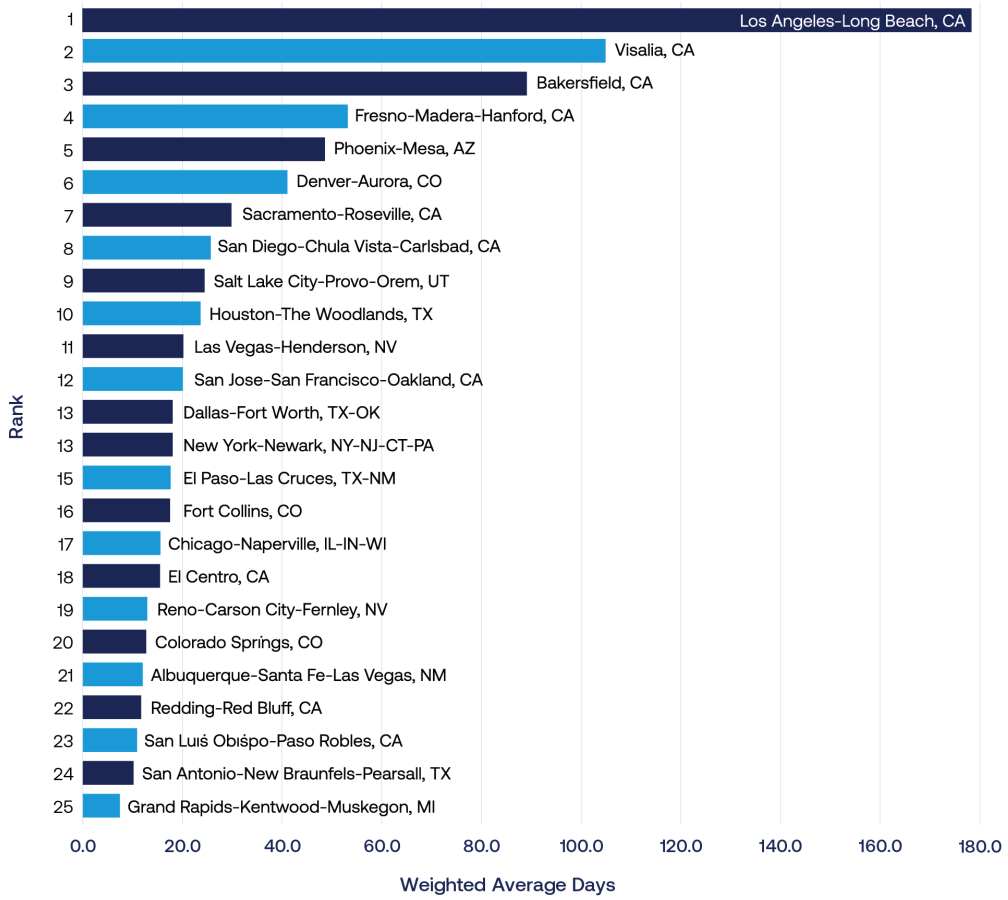


In spite of the promising trend, some trouble signs appear in this year's report, and time will tell whether they are the result of expected fluctuations or more systemic threats. Nationwide, nearly twice as many counties worsened as improved. The weighted average number of unhealthy ozone days of all counties taken together increased by about 6%. And although the number of counties earning "F" grades remained nearly unchanged from the 2023 report, those earning "A" grades dropped by more than 10%, from 302 to 270.

The list of 25 cities with the worst ozone pollution in "State of the Air" 2024 and their order of ranking remained remarkably stable compared with last year's report. The largest change in rank was only 5 places as Dallas-Fort Worth worsened from 18th to 13th worst. This year, Hartford Connecticut was the only city that improved enough to move off the worst 25 list. It was replaced by Grand Rapids, Michigan, which earned a spot on the list for the first time in 8 years. None of the cities on the list reported a worst-ever average number of days of ozone smog. Two cities, Fresno and El Centro, California recorded their fewest-ever number of unhealthy days for ozone, though they still earned "F" grades.

EMBARGOED

25 Cities Most Polluted by Ozone



EMBARGOED

The geographical distribution of cities with the worst ozone problems confirms a pattern seen over nearly a decade of reporting: the great majority are western cities. Cities in the West and the Southwest continue to dominate the list of the most ozone-polluted cities. California retains its position of being the state with the most metro areas on the list, with 10 of the 25 most-polluted cities, while the six states of Arizona, Colorado, Nevada, New Mexico, Texas, and Utah accounted for 12 others. They are joined this year by only three more easterly cities, New York, Chicago, and Grand Rapids.

Although cleanup of ozone precursor pollutants has been working to reduce ozone concentrations, the impact of climate change in the West has meant higher temperatures, dry, sunny skies and more frequent stagnation events that are contributing to the number of unhealthy ozone days being higher than it would otherwise be. Simply, climate change is undercutting the progress we would have made.

Mike Nelson, chief meteorologist at Denver7, goes beyond the seven-day forecast to educate viewers on climate issues. Alongside the daily high temperature and precipitation, his weather graphics include the Denver area's air quality rating and the planet's current amount of carbon dioxide, the heat-trapping gas that's a major contributor to global warming.

He says on-air meteorologists have a special responsibility to talk about climate change.

"The television meteorologist is as close to a scientist as most Americans are going to get. People invite us into their homes every single day to explain something complicated – the weather," Nelson says. "Why would we shy away from talking about the most important thing we face globally?"

Nelson has been forecasting weather in Colorado for more than 30 years. During that time, the Clean Air Act and other regulations have helped improve air quality, he says. But he notes that the increase in large wildfires across the West in recent years is exacerbating particulate matter pollution. A hotter, drier climate is helping to fuel these more intense wildfires and days with heavy smoke, Nelson says.

Although related, climate and weather aren't the same. Climate is the long-term average of conditions, whereas weather refers to short-term changes and is often fast-changing. Nelson uses a football analogy: "Climate is the history of the National Football League; weather is one play in a game."

Nelson says the birth of his first grandchild 11 years ago pushed him to speak more about climate implications. Today's children and future generations are most at risk if we don't reduce carbon emissions, he notes.

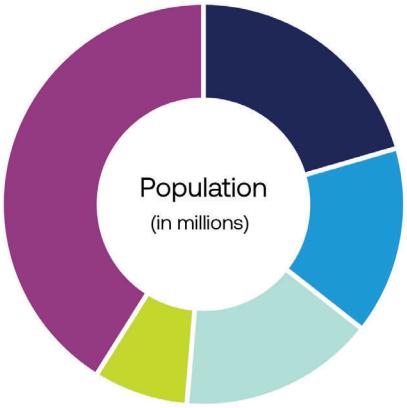
"We can still fix it," Nelson says, "but the clock is ticking, and we should get going on it at a faster pace."

Mike Nelson
Chief Meteorologist at Denver7

EMB

Populations at Risk

Nearly 263 million people live in the 885 counties with enough monitoring data to be assigned a grade for at least one pollutant in this year's report. The majority of U.S. counties actually don't have monitors—which means that many communities, especially rural ones, don't have official monitored information on their air quality. It is important to note that the population numbers included in this section are only for those places that collect air pollution data, and do not reflect the entire population of these groups in the U.S. The availability of data, and hence the population that is included in this report, differs for each pollutant.



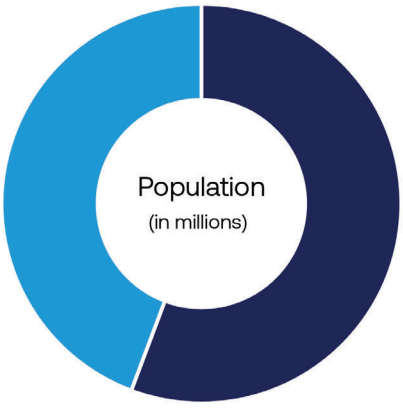
Grade	Population
A	50.3
B	37.0
C	38.5
D	18.6
F	100.6

Population (millions) by County Ozone Grade

Grade	Population
A	49.2
B	64.8
C	41.2
D	7.1
F	65.0

Population (millions) by Daily PM Grade

EMBARGOED



Grade	Population
Pass	114.1
Fail	90.7

Population (millions) by Annual PM Grade

All of the 131.2 million Americans living in places with failing grades for unhealthy levels of ozone or particle pollution are at risk of harm to their health. But some groups of people are especially vulnerable to illness and death from their exposure. *See **People at Risk** for more detail about the factors that contribute to increased risk.*

The number of people in these high-risk groups in "State of the Air" 2024 are as follows:

- **People of color**—About 68.9 million people of color live in counties that received at least one failing grade for ozone and/or particle pollution. Over 27.5 million people of color live in counties that received failing grades on all three measures, including some 16.8 million Hispanics.
- **People experiencing poverty**—Sixteen million people with incomes meeting the federal poverty definition live in counties that received an F for at least one pollutant. More than 5.4 million people in poverty live in counties failing all three measures.
- **Children and older adults**—More than 29.2 million children under age 18 and some 20.6 million adults age 65 and over live in counties that received an F for at least one pollutant. More than 9.7 million children and more than 6.7 million seniors live in counties failing all three measures.
- People with underlying health conditions
  - **Asthma**—More than 1.9 million children and nearly 9.8 million adults with asthma live in counties that received an F for at least one pollutant. More than 600,000 children and some 3.1 million adults with asthma live in counties failing all three measures.
  - **Chronic Obstructive Pulmonary Disease (COPD)**—Some 6.0 million people with COPD live in counties that received an F for at least one pollutant. More than 1.7 million people with COPD live in counties failing all three measures.
  - **Lung Cancer**—More than 55,000 people diagnosed with lung cancer in 2020 live in counties that received an F for at least one pollutant, and about 15,200 people diagnosed with lung cancer live in counties failing all three measures.
  - **Cardiovascular Disease**—More than 8.4 million people with cardiovascular disease live in counties that received an F for at least one pollutant. More than 2.5 million people live in counties failing all three measures.
  - **Pregnancy**—Adverse impacts from air pollution have been shown both for those who are pregnant as well as for the developing fetus. More than 1.4 million pregnancies were recorded in 2022 in counties that received at least one failing grade for particle pollution. Of those, more than 478,000 were in counties that received failing grades for all three measures.

*For more detail about the number of people at risk by grade and by pollutant, see **Data Table 1**. The populations at risk are also included by county in the **State Data Tables**.*

EMBARGOED

Most Polluted Places to Live

In addition to the 25 worst cities for each pollutant listed above, the 25 most polluted counties for ozone and particle pollution are ranked in the tables below.

Ozone Ranking	State	County	WA
1	California	San Bernardino	175.2
2	California	Riverside	128
3	California	Los Angeles	114.8
4	California	Tulare	103

22	Indiana	Marion	11.9
23	Washington	Yakima	11.8
24	California	Sacramento	11.7
24	Michigan	Wayne	11.7

Thirty counties, listed alphabetically by state below, received failing grades for all three measures of pollution:

Arizona	Maricopa, Pinal
California	Alameda, Butte, Contra Costa, Fresno, Imperial, Kern, Kings, Los Angeles, Madera, Merced, Orange, Placer, Riverside, Sacramento, San Bernardino, San Diego, Santa Clara, Shasta, Stanislaus, Sutter, Tehama, Tulare
Colorado	Denver
Michigan	Wayne
Nevada	Clark, Washoe
New Mexico	Bernalillo
Utah	Salt Lake

Cleanest Places to Live

Many cities in the U.S. enjoy air that is considered clean for one or more of the pollution measures tracked in "State of the Air." In this year's report, 55 of the cities for which there is monitoring data had zero high short-term particle days and 75 cities had zero ozone days. Because year-round particle pollution is scored differently, the cleanest cities for this measure can be ranked, and the best 25 are considered cleanest. *See **Data Tables 3a-c**.*

In this year's report, only five cities rank on all three cleanest cities lists for particle pollution and ozone. They had zero days high in particle pollution and in ozone and are among the 26 cities with the lowest year-round particle levels. After last year's one-time appearance on all three cleanest lists, Asheville and Greenville, NC and Rochester NY all lost their place this year because of increases in ozone smog pollution. The other four again repeat their appearance on the combined list this year. Only Johnson City-Kingsport-Bristol, TN-VA, in its debut, was added to the list.

Listed alphabetically, the cleanest cities are:

Bangor, ME

Johnson City-Kingsport-Bristol, TN-VA

Lincoln-Beatrice, NE

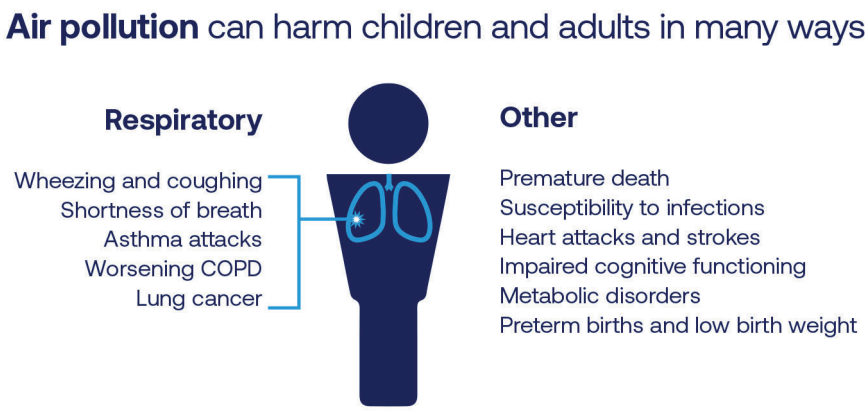
Urban Honolulu, HI

Wilmington, NC

EMBARGOED

Health Impact of Air Pollution

Years of scientific research have clearly established that particle pollution and ozone are a threat to human health at every stage of life, increasing the risk of premature birth, causing or worsening lung and heart disease, and shortening lives. Some groups of people are more at risk of illness and death than others, because they are more likely to be exposed, or are more vulnerable to health harm, or often both.



Health Effects of Particle Pollution

Particle pollution—also known as particulate matter or soot—is a deadly and growing threat to public health in communities around the country. The more researchers learn about the health effects of particle pollution, the more dangerous it is recognized to be.

What is particle pollution?

Particle pollution refers to a mixture of tiny bits of solids and liquids in the air we breathe. Particle pollution comes from many sources. Factories, power plants, and diesel- and gasoline-powered vehicles and equipment either directly emit fine particles or generate other pollutants, such as nitrogen oxides (NO_x) and sulfur oxides (SO_x), known as precursors because they can then form into fine particles in the atmosphere. Other sources of particle pollution include wildfires, burning wood in wood stoves or residential fireplaces and burning biomass for electricity.

Researchers and regulators categorize particles according to size, grouping them as coarse, fine and ultrafine. Coarse particles, called PM10, can include wind-blown dust, ash, pollen and smoke. Fine particles, $PM_{2.5}$, are most often a by-product of burning wood or fossil fuels, and may include components such as toxic compounds, salts and metals. The tiniest are called ultrafine particles, or $PM_{0.1}$. They are also produced by combustion, and are included in the larger category of $PM_{2.5}$.

Individual fine particles are too small to be visible, but when pollution levels are high, they can make the air appear thick and hazy.

The differences in size make a big difference in how particles affect our health. Our bodies' natural defenses help us to keep the coarse particles we inhale out of the deepest parts of our lungs, although these particles do deposit in the larger airways. However, those defenses do not keep smaller fine or ultrafine particles from penetrating deep into the lungs and even all the way into the air sacs. Many of these particles get trapped there, while the smallest are so tiny that they can pass from the air sacs into the bloodstream and disperse to other organs of the body.

EMBARGOED

What can particles do to your health?

Particle pollution can be very dangerous to breathe, especially at higher concentrations. It can trigger illness, hospitalization and premature death. Researchers estimate that $PM_{2.5}$ is responsible for nearly 48,000 premature deaths in the United States every year.[1]

Short-Term Exposure

Short-term spikes in particle pollution that last from a few hours to a few days can kill. Premature deaths from breathing these particles can occur on the very day that particle levels are high, or up to a month or two afterward. Most premature deaths are from respiratory and cardiovascular causes. Particle pollution does not just make people die a few days earlier than they might otherwise—in many cases these deaths would not have occurred for years if the air were cleaner.[2]

Studies linking short-term exposure to $PM_{2.5}$ to death from all causes have been accumulating for a number of years. Taken together, this body of research provides consistent evidence of positive associations between particle pollution and mortality across diverse geographic locations and in populations with a wide range of demographic characteristics. In 2019, an international study looking at 499 cities across the globe reinforced these consistent findings.[3]

Exposure to even low levels of fine particles can be deadly. Looking nationwide in a 2017 study, researchers found that older adults faced a higher risk of premature death even when levels of short-term particle pollution remained well below the current national standard. This was consistent whether the older adults lived in cities, suburbs or rural areas.[4] Another study published in 2018 analyzed mortality data from 135 U.S. cities and found a causal relationship with exposure to $PM_{2.5}$ at concentrations below the federal standard.[5]

Particle pollution also has many other harmful effects, ranging from decreased lung function to heart attacks. Extensive research has linked short-term increases in particle pollution to:

- increased mortality in infants;[6]
- increased hospital admissions for cardiovascular disease, including heart attacks and strokes;[7]
- increased hospital admissions and emergency department visits for chronic obstructive pulmonary disease (COPD);[8]
- increased severity of asthma attacks and hospitalization for asthma among children.[9,10]

EMBARGOED

Year-Round Exposure

Decades of research have firmly established that breathing particle pollution day in and day out can also be deadly. Across numerous seminal studies that looked at different groups of people living in different parts of the country, the results consistently showed a clear relationship between long-term exposure to particulate matter and mortality.[11]

Research using publicly available data on a cohort of more than one million adults in the U.S. reconfirmed that long-term exposure to $PM_{2.5}$ was associated with elevated risks of early death. The increased risk was primarily associated with death from cardiovascular and respiratory causes, including heart disease, stroke, influenza and pneumonia. Researchers also found a similar association between exposure to fine particle pollution and an increased risk of death from lung cancer among never-smokers.[12] Another study of 68.5 million Medicare-enrolled adults in the United States between 2000 and 2016 found a 6-8% increase in risk of all-cause mortality for every 10µg/m3 increase in the annual average $PM_{2.5}$.[13]

Research has also linked year-round exposure to particle pollution to a wide array of serious health effects at every stage of life, from conception through old age. Among individuals who are pregnant, fetuses and children, long-term particle pollution exposure is linked to:

- Increased risk of preterm birth and low birth weight;[14]
- Increased fetal and infant mortality;[15]
- Impaired neurological development and cognition;[16]
- Reduced lung development and impaired lung function in children;[17]
- Higher likelihood of children developing asthma.[18]

In adults, long-term particle pollution exposure is linked to:

- Increased risk from existing cardiovascular and respiratory disease, including a worsening of heart disease, atherosclerosis and COPD;[19,20]
- Higher likelihood of developing diabetes and subsequent complications;[21,22]
- Higher likelihood of getting lung cancer and of dying from it;[23]
- Impaired cognitive functioning and an increased risk of Parkinson's disease, Alzheimer's disease and other dementias later in life;[24,25]
- Increased risk of clinical depression and anxiety.[26]

The good news is that cleaning up particle pollution makes a difference. Research has shown a consistent relationship between decreasing $PM_{2.5}$ concentrations and improving respiratory health in children and reduced mortality of adults in communities that have reduced their levels of year-round particle pollution.[27,28]

EMBARGOED

Who is most at risk from particle pollution?

Anyone who lives where particle pollution levels are high is at risk. Some people face greater risk, however, based on their underlying health and other characteristics. [See the People at Risk section for more information about vulnerable groups] Research has shown that the groups at the greatest risk from particle pollution include:

- Pregnant people and fetuses;[29]
- Infants, children and people age 65 and older;[30]
- People with lung disease, especially asthma, but also people with COPD;[31]
- People with cardiovascular disease;[32]
- People with lung cancer;[33]
- People of color;[34]
- Current or former smokers;[35]
- People with low incomes;[36] and
- People who are obese or have diabetes.[37]

Health Effects of Ozone Pollution

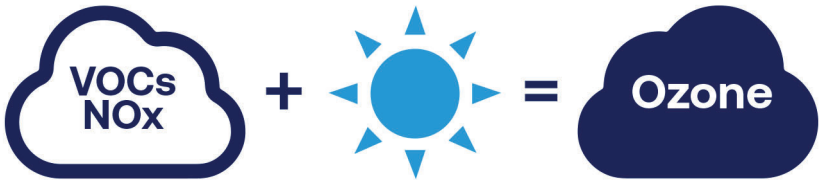
Ground-level ozone, sometimes known as smog, is one of the most widespread and dangerous pollutants in the United States. Scientists have studied the effects of ozone on human health for decades. Hundreds of studies have confirmed that ozone harms people at levels currently found in many parts of the United States.

What is Ozone Pollution?

Ozone is a gas composed of molecules with three oxygen atoms. (The oxygen we need for life is made up of molecules with two oxygen atoms.) Ozone forms in the lower atmosphere when a combination of pollutants, usually nitrogen oxides (NO_x) and volatile organic compounds (VOCs), "cook" together in sunlight through a series of chemical reactions. NO_x and VOCs are produced primarily when fossil fuels such as gasoline, diesel, oil, natural gas or coal are burned or when solvents and some other chemicals evaporate. NO_x is emitted from power plants, motor vehicles and other sources of high-heat combustion. VOCs are emitted from motor vehicles, oil and gas operations, chemical plants, refineries, factories, gas stations, paint, consumer products and other sources.

If these ingredients are present under the right conditions, they react to form ozone. Sunlight is key, with higher temperatures increasing ozone production. Because the reactions take place in the atmosphere, ozone often shows up downwind of the sources of the original emissions, sometimes many miles from where it formed.

Ozone air pollution is sometimes called ground-level ozone, to distinguish it from the much higher-altitude stratospheric ozone layer that protects people from damaging ultraviolet rays from the sun.



What Can Ozone Pollution Do to Your Health?

Ozone gas is a powerful lung irritant. When it is inhaled into the lungs, it reacts with the delicate lining of the small airways, causing inflammation and other damage that can impact multiple body systems. Ozone exposure can also shorten lives.

Ozone has a serious effect on the respiratory system, both in the short term and over the course of years of exposure.

When ozone levels are high, many people experience breathing problems such as chest tightness, coughing and shortness of breath, often within hours of exposure. Even healthy young adults may experience respiratory symptoms and decreased lung function.[38]

Other breathing problems that have been tied to short-term exposure to ozone include:

- Worsening of symptoms, increased medication use, and increased emergency department visits and hospital admissions for people with asthma and COPD;[39]
- Susceptibility to respiratory infections such as pneumonia, resulting in an increased likelihood of emergency department visits and hospitalizations.[40]

Living with ozone pollution long term may cause lasting damage to respiratory health, including:

- Development of new cases of asthma in children;[41]
- Damage to the airways, leading to development of COPD;[42]
- Increased allergic response.[43]

The inflammation and systemic stress caused by short- and long-term exposure to ozone can also do damage to tissues, genes and proteins throughout the body, which can cause or worsen other disease conditions over time. These include:

- Potential increased risk of metabolic disorders, including glucose intolerance, hyperglycemia and diabetes;[44]
- Potential impact on the central nervous system, including brain inflammation, structural changes and increased risk of cognitive decline;[45,46]
- Increased likelihood of reproductive and developmental harm, including reduced fertility, pregnancy complications, preterm birth, stillbirth and low birth weight;[47,48]
- Possible cardiovascular effects.[49]

The damage ozone does to the body can be deadly. Recent research has affirmed earlier findings that short-term exposure to ozone, even at levels below the current standard, likely increases the risk of premature death, particularly for older adults.[50] There is also a growing body of evidence that long-term exposures to ambient ozone may be associated with an increased risk of cardiovascular and respiratory disease mortality.[51]

EMBARGOED

Who is Most at Risk from Ozone Pollution?

Anyone who spends time outdoors where ozone pollution levels are high may be at risk. Some people face a higher-than-average risk, however, because of their underlying health and other characteristics. [See the People at Risk section for more information about vulnerable groups.] Research has shown that the groups at greatest risk from ozone pollution include:

- Pregnant people and fetuses;[52]
- Children;
- Anyone 65 and older;
- People with existing lung disease such as asthma and COPD;
- People who work or exercise outdoors.[53]

Air Pollution and COVID-19

Both ozone and particle pollution can impact the functioning of the immune system and increase susceptibility to respiratory infections. Air pollution also increases the risk of chronic lung and cardiovascular diseases that put people at higher risk of poor outcomes from COVID-19. It should come as no surprise, then, that a growing body of research has found an association between exposure to even low levels of air pollution and an increased risk of severe illness and death from COVID-19. People living with chronic conditions, the elderly, people of color and those living in low-wealth communities are more vulnerable to poor outcomes.[54,55] A 2022 study in California found that people living in the most polluted areas of the state had a 20% higher risk of COVID infection and a 51% higher risk of death than residents in the least polluted areas.[56]

People at Risk

The health burden of air pollution is not evenly shared. Some people are more at risk of illness and death from air pollution than others. Several key factors affect an individual's level of risk:

- Exposure—Where someone lives, where they go to school and where they work makes a big difference in how much air pollution they breathe. In general, the higher the exposure, the greater the risk of harm.
- Susceptibility—Individuals who are pregnant and their fetuses, children, older adults and people living with chronic conditions, especially heart and lung disease, may be physically more susceptible to the health impacts of air pollution than other adults.
- Access to healthcare—Whether or not a person has health coverage, a healthcare provider, and access to linguistically and culturally appropriate health information may influence their overall health status and how they are impacted by environmental stressors like air pollution.
- Psychosocial stress—There is increasing evidence that non-physical stressors such as poverty, racial/ethnic discrimination and migration status can amplify the harmful effects of air pollution.

These risk factors are not mutually exclusive and often interact in ways that lead to significant health inequities among subgroups of the population. Taken all together, these high-risk categories account for a large proportion of the U.S. population.

EMBARGOED

People of color

Research has shown that people of color are more likely to be exposed to air pollution and more likely to suffer harm to their health from air pollution than white people.[57,58] Much of this inequity can be traced to the long history of systemic racism in the United States. Practices such as redlining, the discriminatory outlining of so-called "riskier" neighborhoods by mortgage lenders, institutionalized residential segregation in the 20th century, impairing the ability of many people of color to build wealth and limiting their mobility and political power. Over the years, decision-makers have found it easier to place sources of pollution, such as power plants, industrial facilities, landfills and highways, in economically disadvantaged communities of color than in more affluent, predominantly white neighborhoods. The resulting disproportionate exposure to air pollution has contributed to high rates of emergency department visits for asthma and other diseases.[59,60]

People of color are also more likely than white people to be living with one or more chronic conditions that make them more susceptible to the health impact of air pollution, including asthma and diabetes.[61]

People experiencing poverty

There is evidence that having low income or living in lower income areas puts people at increased risk from air pollution, although the correlation is not as strong as with race and ethnicity.[62,63] People living in poverty are more likely to live in close proximity to sources of pollution and have fewer resources to relocate than people with more financial security.[64] Poverty itself, along with the problems that beset many low-income communities, such as lack of safety, green space, and high-quality food access, have been associated with increased psychosocial distress and chronic stress, which in turn make people more vulnerable to pollution-related health effects.[65] People with low income also have lower rates of health coverage and less access to quality and affordable health care to provide relief to them when they get sick.

Dr. Aaron Levy works directly with those who are among the most vulnerable to poor air quality—children.

"The impacts of poor air quality start prenatally," says Levy, a pediatrician at Atrium Health's Levine Children's Hospital in Charlotte, North Carolina. "We know that women who are exposed to higher levels of poor air quality including particulate pollution have a greater risk of having babies born premature and low birth weight."

Levy is an advocate for integrating climate health into medical training. He says the impacts of air pollution on people's health should be as ingrained in education as the effects of cigarette smoke.

When physicians understand how climate change is related to patient care, they're better equipped to help protect and educate patients, he says. For example, Levy points to the Air Quality Index as a tool that people with asthma and other respiratory diseases can use to prepare for days when they may need to limit their outdoor exposure.

Levy says air quality has improved in recent years in the Charlotte area due to policy and behavioral changes but that continuing to push for cleaner energy and transportation is critical to healthier air. He adds that warming temperatures has been linked to longer and more intense allergy seasons, worsening the impacts of asthma.

"This past summer was a perfect example that we do not live in a vacuum," Levy says, noting that wildfire smoke from Canada reached the Carolinas. "We're all globally interconnected with the effects of climate change and we all play a role to help ensure every child grows up breathing healthy air."

EMB

Children

Children are both more susceptible to harm from air pollution and more likely to be exposed than adults. The growth and development of a child's lungs and breathing ability start in utero and continue into early adulthood. Long-term exposure to particle pollution during pregnancy and early childhood has been linked to reduced lung growth and long-term exposure to ozone has been linked to increased potential for the development of asthma. The developing brain and heart may also be affected, with life-long consequences.[66] In addition, the body's defenses that help adults fight off infections are still developing in children. Children have more respiratory infections than adults, which also seems to increase their susceptibility to air pollution.[67]

Children breathe more rapidly and inhale more air relative to their size than do adults. They are more likely to spend time outdoors, running around, being active and breathing hard. Consequently, they are more exposed to polluted outdoor air than adults typically are.

Older adults

Much of the illness and premature death caused by air pollution occurs in older adults, who are at increased risk of harm for several reasons. As a person ages, the normal process of thinning and weakening of the lung tissue and the supporting muscle and bones of the ribcage results in diminishing lung function over time. The impairment that results from exposure to air pollutants then has an add-on effect, putting stress on the lungs and heart. Older people are also more likely to be living with chronic diseases, and there is evidence that co-existing chronic lung, heart or circulatory conditions may worsen following exposure to environmental pollutants.[68]

The strength of the immune system also declines with age, leaving older people at greater risk of contracting infections and less able to get them under control before they become serious. Because exposure to air pollution increases susceptibility to respiratory infections, it also increases the risk of severe illness and death in older adults.

People with underlying health conditions

For the millions of people in the U.S. living with illnesses such as asthma, COPD, diabetes, heart disease and lung cancer, exposure to air pollution places them at greater risk of harm to their health than those without disease. The cellular injury and systemic inflammation triggered by breathing ozone and particle pollution put additional stress on people's lungs, heart and other organs already compromised by disease. This can result in a worsening of symptoms, increased medication use, more frequent emergency department visits and hospitalizations, an overall reduced quality of life and far too often premature death.

Individuals who are pregnant and fetuses

Pregnancy is always a susceptible time for both the individual who is pregnant and the developing fetus. The pregnant body undergoes dramatic physiological changes in hormone levels, metabolism and circulation throughout months of gestation. The rapid and complex development of the fetus is a precisely timed and sequenced process. The inflammation and oxidative stress resulting from exposure to air pollution during pregnancy can increase the risk of hypertensive disorders, including preeclampsia, and lead to intrauterine inflammation and damage to the placenta that can disrupt the growth and development of the fetus. Fetal health may also be impacted in a number of ways by environmental contaminants that have been shown to cross the placenta.[69]

Exposure to both ozone and particle pollution during pregnancy is associated with premature birth, low birth weight and stillbirth. These risks are amplified when the individual who is pregnant is also at higher risk of health harm from air pollution in other ways, such living in poverty or having asthma.[70]

People with a smoking history

There is some recent evidence suggesting that current and former smokers are at greater risk of health harm from exposure to fine particle pollution compared with never-smokers. They are more likely to develop lung cancer and to die prematurely.[71] Smoking damages the lungs, heart, blood vessels and other organs.[72] This impairment leaves the person with a smoking history more vulnerable to the health impact of air pollution than a never-smoker.

EMBARGOED

Recommendations for Action

We need action at every level to clean up air pollution and address climate change.

Federal Government

The Biden administration has made major progress on protecting public health and advancing environmental justice through their efforts to tackle the climate crisis and clean up the air. In "State of the Air" 2023, we called for the U.S. Environmental Protection Agency to finalize a suite of lifesaving clean air measures. Many of those policy measures are now in place, and other critical protections are well underway.

- **DONE: Updated national particle pollution standards.** EPA strengthened the annual fine particulate matter pollution standards from 12 µg/m3 to 9 µg/m3. While the standards aren't as strong as what the Lung Association called for, they'll still save lives and prevent significant health harms.
- **DONE: Rules to clean up methane and other air pollutants from the oil and gas industry.** EPA finalized rules to address leaks of methane from the oil and gas production process, like drilling operations. This is a crucial climate measure and will also reduce emissions of dangerous volatile organic compounds (VOCs). This is especially important for people living near oil and gas sites, making this final rule an environmental justice victory as well as a climate victory.
- **DONE: Stronger multi-pollutant standards for future cars.** EPA finalized a rule that will make future light- and medium-duty vehicles cleaner. The rule will help get more zero-emission vehicles on the road and make new gasoline-powered cars less polluting too.
- **DONE: Stronger carbon pollution limits on future trucks and buses.** EPA finalized a rule that will make future heavy-duty vehicles less polluting. The rule tightens emissions limits of the carbon pollution that drives climate change and will help drive a transition to zero-emission trucks and buses, a win for environmental justice.
- **IN PROGRESS: Implementing the largest-ever climate and clean energy investments passed in the Inflation Reduction Act.** This landmark law is the largest action the U.S. has ever taken to tackle climate change. Investments in clean electricity, electric vehicles, zero-emission appliances, air quality monitoring, environmental justice and more are rolling out.
- **IN PROGRESS: Addressing wildfires.** The Biden Administration created a Wildland Fire Mitigation and Management Commission, which released a report with recommendations for federal action to address the nation's accelerated and climate-driven wildfire crisis. We're pushing for many of those recommendations to be adopted.

We applaud this progress. Now, we call for President Biden and EPA to build on these successes with additional final rules to clean up air pollution, and on Congress to help ensure these protections are funded, implemented and enforced. Additional actions needed include:

- **EPA must set stronger national standards for ozone**. The research shows that a standard of no higher than 60 parts per billion would protect health. Stronger standards would drive cleanup of polluting sources nationwide and enable families across the country to be better informed about when local air quality may put their health at risk. In 2023, EPA announced a major delay by essentially starting over in their work to update the standard. There is no time to waste in moving forward. Take action at Lung.org/sota-petition.

EMBARGOED

- **EPA must clean up power plant pollution.** EPA must finalize rules to limit carbon emissions on coal and gas-fired power plants. These measures will help address climate change and provide important reductions in other pollutants at the same time. EPA must also finalize tighter limits on mercury and other toxic emissions from coal- and oil-fired power plants, and strengthen monitoring requirements to help ensure that cleanup happens quickly.
- **Congress must defend the Clean Air Act and its protections and pass funding bills that adequately invest in EPA.** There are partisan efforts underway to undermine federal clean air protections and the Clean Air Act itself. Congress must safeguard the Clean Air Act and the administration's efforts to clean up deadly air pollution and climate pollution. Congress must also increase funding for EPA to set and enforce these lifesaving rules and to provide assistance to state, local and Tribal air agencies to monitor and clean up harmful air pollution.

State, Territorial and Tribal Governments

Not only can states, territories and Tribes strengthen clean air protections, they are crucial to the success of EPA's stronger standards, and they can reap the benefits of Inflation Reduction Act investments.

- **Implement EPA's new clean air protections.** EPA's final rules require work from states, territories and Tribes to ensure their residents see the benefit of stronger air pollution standards. This includes cleaning up areas where the air violates the new particle pollution standards, writing plans to clean up carbon from the power sector and implementing the recently finalized limits on methane.
- **Set a clean or renewable electricity standard or clean peak** standard that phases out the use of coal, oil, methane gas (often called natural gas) and other combustion energy sources and replaces it with wind, solar, geothermal and tidal and other non-combustion forms of electricity. Do not allow for the increased use of biomass or municipal solid waste for electricity because of their contributions to dangerous air pollution.
- **Prioritize deployment of clean energy production.** In order to hit clean energy goals, it is imperative for states, territories and Tribes to prioritize major deployment of non-combustion clean power as well as battery energy storage.
- **Leverage Inflation Reduction Act funding** available to state, territorial and Tribal governments to reduce emissions, including reducing air pollution at ports, investing in zero-emission school buses, electrifying buildings, expanding electric vehicle infrastructure, and improving air quality monitoring. Ensure that environmental justice communities that have long borne the brunt of pollution impacts are prioritized for investment.
- **States: Use Clean Air Act authority to adopt the California zero-emissions standards for cars and trucks.** These include California's Low-Emission Vehicle criteria pollutant and greenhouse gas regulations; Zero-Emission Vehicle regulations; and Advanced Clean Trucks regulations.

EMBARGOED

Evelyn Mateos racks up around 1,000 miles each month driving between her home in Orange County, California and Las Vegas, where she lived for a few years until recently.

"In Southern California, we're built on cars. We drive pretty much everywhere," she says.

But a proposed high-speed electric train connecting Las Vegas and suburban San Bernardino County near Los Angeles would give people another option for traveling. Construction on the 218-mile Brightline West project is expected to start this year.

The zero-emission system is projected to lower greenhouse gasses by more than 400,000 tons of CO2 each year and reduce annual vehicle miles traveled by more than 700 million, according to Brightline[iii]. Traveling at speeds of up to 200 miles an hour, the trains would be nearly twice as fast as driving.

Mateos says she believes many people in Southern California care about reducing pollution from vehicles and that an alternative to driving or flying to Las Vegas would be appealing.

"Not having to put those miles on your car and risk getting stuck in traffic could be exciting for Californians," she says. "It could potentially get many cars off the road."

Evelyn Mateos
Orange County, CA

EMBARGO

Local Governments

Local governments have the power to help ensure that city and county operations are zero-emission and that residents have the ability to choose zero-emission forms of transportation and electricity. These actions must benefit the communities most impacted by unhealthy air.

- **Adopt a climate action plan.** Reduce city- and county-wide emissions by supporting walking, biking and transit and zero-emission vehicle infrastructure and ensuring that building and parking policies support these goals. Include measures to address the impacts of climate change on residents, including health impacts. Under the Inflation Reduction Act, municipalities can opt in to get federal planning grants to reduce climate pollution.
- **Purchase zero-emission fleet vehicles.** Commit to purchasing zero-emission garbage and recycling trucks, transit buses, school buses and other vehicles. Under the Inflation Reduction Act, there are tax credits for the purchase of new and used electric vehicles that are available through up-front direct pay, as opposed to in a tax filing. EPA also has a Clean School Bus Program that has provided several rounds of rebates and grant programs to eligible entities purchasing zero-emission school buses.
- **Establish purchasing goals for renewable, non-combustion electricity.** Power city and county operations with truly clean sources of electricity like wind, solar, geothermal or tidal. The Inflation Reduction Act also included direct-pay tax credits for the purchase of renewable energy.

iii https://wwwbrightlinewest.com/overview/project

Individuals

You can take action to protect yourself and your family from the dangers of air pollution. Regardless of its grade or ranking in this report, any community can experience days with unhealthy levels of air pollution. Some simple precautions will reduce your risk:

- **Check daily air pollution forecasts in your area at airnow.gov.** The color-coded forecasts let you know when the air is unhealthy in your community. When the air is bad, move your exercise plans and other activities indoors. If you live in a fire-prone area, learn more about using N-95 masks and creating a clean room inside your home with our wildfire resources at Lung.org/wildfire.
- **Reduce your own contributions to air pollution.** Prioritize walking, biking and clean public transit over diesel or gasoline-powered vehicles. Conserve electricity and purchase your power from clean, non-combustion sources if you can. When heating and cooling, adjusting your thermostat just one degree can save you money and reduce energy use. Don't burn leaves or trash and avoid burning wood whenever possible.
- **Consider taking advantage of tax incentives to reduce emissions from your home and vehicle.** One of the best ways to reduce pollution is to switch from vehicles and appliances that burn fuel—like gasoline-powered cars and natural gas stoves and furnaces—to zero-emission versions that run on electricity. Under the Inflation Reduction Act passed in 2022, you may be able to get tax credits for buying a new or used electric vehicle or for upgrading your home with efficient, zero-emissions appliances like induction stoves or heat pumps. Learn more here.
- **Show up at the local level.** In addition to taking action with the Lung Association, you can advocate for air quality and climate policy change in your community. Get engaged with local policymakers and civic organizations. Learn about local advocacy opportunities. Show up at public hearings and meet with your local leaders to share why cleaning up air pollution and addressing climate change matters to you and your community. You are the best advocate for action in your community.

EMBARGOED

Rohan Arora watched his father coughing at home and relying more on his inhaler. Smog and other air pollution he encountered while commuting to and working in Washington, D.C. aggravated his asthma to the point that sleeping became difficult.

Seeing the toll that poor air quality took on his father inspired Arora to make environmental health and climate activism his passion.

"When you see it in your own household, it becomes real," Arora says. "It's not something in the news, it's not hypothetical – you see it happening in front of you."

Arora is the founder and executive director of The Community Check-Up, a national environmental health organization that empowers youth to be changemakers in their communities. He says grassroots efforts are instrumental in driving change and that young people can play a big role by discussing climate issues at home, attending town halls, and talking with local representatives.

Schools can also help educate on environmental and climate topics, he says, by integrating them into the curriculum so that students gain the skills needed to understand the most pressing challenges and instill change.

"Young people have a lot of energy," Arora says, "and that's what this movement really needs."

Rohan Arora
Executive Director of The Community Check-Up

Understanding Grades and Tables

*See **Methodology** for a full explanation of data sources and calculations made for state grades.*

Notes for state grades tables

1. Not all counties have monitors for either ozone or particle pollution. If a county does not have any monitoring data for either pollutant, that county's name is not on the list in these tables. The decision about siting monitors in a county is made by the state and the U.S. Environmental Protection Agency, not by the American Lung Association.
2. **INC** (Incomplete) indicates that monitoring data is available for at least one year in that county, but not all three years.
3. **DNC** (Data Not Collected) indicates that data on that particular pollutant was not collected in that county during the three years covered in the report.
4. The **Weighted Average (Wgt. Avg.)** was derived by adding the three years of individual level data (2020-2022), multiplying the sums of each level by the assigned standard weights (i.e., 1=orange, 1.5=red, 2.0=purple and 2.5=maroon) and calculating the average. Grades are assigned based on the weighted averages as follows: A=0.0, B=0.3-0.9, C=1.0-2.0, D=2.1-3.2, F=3.3+.
5. The **Design Value** is the calculated concentration of a pollutant based on the annual National Ambient Air Quality Standard for PM2.5, which is 9 µg/m3. Counties with design values of 9.0 or lower received a grade of "Pass" for Annual $PM_{2.5}$. Counties with design values of 9.1 or higher received a grade of "Fail."

Notes for at-risk groups tables

1. Adding across rows does not produce valid estimates. Adding the at-risk categories (asthma, COPD, poverty, etc.) will double-count people who fall into more than one category.
2. **Total Population** is based on 2022 U.S. Census and represents the at-risk populations in counties with ozone or $PM_{2.5}$ pollution monitors; it does not represent the entire state's sensitive populations.
3. Those **18 & under** and **65 & over** are vulnerable to ozone and $PM_{2.5}$. Do not use them as population denominators for disease estimates—that will lead to incorrect estimates.
4. **Pediatric asthma** estimates are for those under 18 years of age and represent the estimated number of people in that age group who had asthma in 2022 based on the state rates, when available, or national rates when not (Behavioral Risk Factor Surveillance System, or BRFSS), applied to county population estimates (U.S. Census).
5. **Adult asthma** estimates are for those 18 years of age and older and represent the estimated number of people in that age group who had asthma during 2022 based on state rates (BRFSS) applied to county population estimates (U.S. Census).
6. **COPD** estimates are for adults 18 and over who had ever been diagnosed with chronic obstructive pulmonary disease, which includes chronic bronchitis and emphysema, based on state rates (BRFSS) applied to county population estimates (U.S. Census).
7. **Lung cancer** estimates are for all ages and represent the estimated number of people newly diagnosed with lung cancer in 2020 based on state rates (StateCancerProfiles.gov) applied to county population estimates (U.S. Census).
8. **Cardiovascular (CV) disease** estimates are for adults 18 and over who have been diagnosed within their lifetime, based on state rates (BRFSS) applied to county population estimates (U.S. Census). CV disease includes coronary heart disease, stroke and heart attack.
9. **Pregnancy** estimates are for females 18-49 and based on state rates of pregnancies resulting in live births applied to population estimates (U.S. Census).
10. **Poverty** estimates include all ages and come from the U.S. Census Bureau's Small Area Income and Poverty Estimates program. The estimates are derived from a model using estimates of income or poverty from the Annual Social and Economic Supplement and the Current Population Survey, 2021. Puerto Rico poverty estimates come from the U.S. Census Bureau's American Community Survey, 2018-2022.
11. **People of color** are defined as anyone Hispanic or as non-Hispanic Black, Asian, American Indian/Alaska Native, Native Hawaiian and Other Pacific Islander, or two or more races, based on 2022 county population estimates (U.S Census). Puerto Rico race and ethnicity estimates come from the U.S. Census Bureau's American Community Survey, 2018-2022.
12. Based on a request from Connecticut, the Census Bureau shifted from providing population estimates by county to county-equivalent Planning Regions for the state starting with 2022 data. As air quality data continues to be county-based and Planning Regions are incompatible with historic Connecticut counties, Census Bureau population estimates from 2021 are used in this year's report. Disease rates are still from the latest year available.

Notes:

Cities are ranked using the highest design value for any county within that Combined Metropolitan Statistical Area or Metropolitan Statistical Area.

Adding across rows does not produce valid estimates. Adding the disease categories (asthma, COPD, etc.) will double-count people who have been diagnosed with more than one disease.

Table 2c People at Risk in 25 Most Ozone-Polluted Cities
